Venture Capital Best Practice Strategies To Reduce Economic Uncertainty In Biofuel Investing

David A. Blum, DBA, Northcentral University, USA

ABSTRACT

Independent venture capital firms require actionable economic best practice strategies to reduce uncertainty when investing in biofuel firms. Biofuels derived from plant oils are a primary source of renewable fuel energy replacing petrol diesel. Investing in biofuels is fraught with high capital start-up costs and inaccurate portfolio firm valuation models lessening venture capital personnel ability to achieve higher levels of successful biofuel firm exits. The gap in literature addressed in this paper is venture capital best practice strategies to reduce economic uncertainty in biofuel firms investing are an unexplored phenomenon. Reducing and prospering from the effects economic uncertainty requires venture capital firms to implement best practice strategies. This paper provides venture capital firms with best practice strategies to reduce economic uncertainty when investing in biofuel firms. Utilizing multiples, net present value, internal rate of return, and venture capital model for establishing a valuation price for portfolio firms are actionable economic best practice strategies addressed in this paper. The best practice strategies presented in this paper might reduce economic uncertainty, increase the number of successful exits, and encourage increased funding of biofuel energy firms, contributing to cleaner and healthier communities throughout the United States.

Keywords: Biofuel Investing; Independent Venture Capital (IVC); Venture Capital

INTRODUCTION

The U.S. economy requires reliable and inexpensive sources of energy to fuel economic growth and to create wealth. Locating reliable, abundant, and sustainable sources of energy is critical to the nation's economic, social, and environmental development (Singh, Nigam, & Murphy, 2011). One sustainable and reliable source of fuel energy is biofuels.

The use of biofuels is a promising sustainable source of energy to replace petrol diesel while meeting existing and future transportation fuel needs (Bajhaiya, Mandotra, Suseela, Toppo & Ranade, 2010; Demirbas, 2008; Hossain, Salleh, Boyce, Chowdhury & Naquiuddin, 2008; Singh et al., 2011). Biofuels are a renewable energy source derived from plant-like sources that can be used for heat and fuel (Brennan & Owende, 2009). Plant-like sources include jatropha, corn oil, canola, soybean, palm oil, and algae. Biofuels could play an essential role in replacing petroleum as a viable alternative in reducing long-term carbon dioxide emissions (Brennan & Owende, 2009; Singh et al., 2011).

For biofuel firms to transition from concept to fuel production requires funding in advance of \$10 million just for capital start-up costs (Gallagher, 2011). Acquiring funding in the millions of dollars requires biofuel firms to partner with independent venture capital firms (IVC). IVCs are the primary source of funding for entrepreneurial oriented biofuel firms (Li & Zahra, 2012). IVC firms fund high risk, market scalable, and high growth ventures (Olsson, Frydenberg, Jakobsen, & Jessen, 2010).

Investing in biofuels is fraught with high capital start-up costs and inaccurate portfolio firm valuation models lessening venture capital personnel ability to achieve higher levels of successful biofuel firm exits. Reducing and prospering from the effects of these uncertainties requires IVC firms to implement best practice strategies. In this paper, I focused on best practice strategies IVCs can use to reduce economic uncertainty in biofuel investing.

LITERATURE REVIEW

IVC best practice strategies to reduce economic uncertainty in biofuel firms investing is unexplored in the extant peered literature. The literature is replete with strategies to reduce asymmetry of information vis-à-vis portfolio firm by utilizing staging, due diligence, and monitoring portfolio firm performance (Schertler & Tykvova, 2011; Wiltbank, 2005; Zhang, 2011).

Staging

Staging is a common practice and an vital activity to reduce uncertainty by limiting negative financial exposure in subsequent staging rounds, reducing the effects of asymmetry of information, and preventing the funding of low return on investment projects (Dahiya & Ray, 2012; Geronikolaou & Papachristou, 2011; Hsu, 2010; Smolarski & Kut, 2011). IVC firms face maximum risk in the staging process during the initial round of financing (Smolarski & Kut, 2011). By staging, the IVC firm invests capital and provides additional value-added services to the portfolio firm (Smolarski & Kut, 2011). Wiltbank, Read, Dew, and Sarasvathy (2009) and Dahiya and Ray (2012) indicated that staging mitigates moral hazard by avoiding the introduction of significant portions of funding at the beginning of a project. Hsu found the level of the risk-free interest rate is not a major determinant in the timing of funding at a particular stage. Incremental financing helps the IVC to define goals, monitor the progress of the portfolio firm, and provides the IVC with the option to abandon a project, to delay further investment in a project that is not performing to agreed to standards, or to invest in the opportunity (Driouchi, Leseure, & Bennett, 2009; Rajan, 2010; Smolarski & Kut, 2011).

Due Diligence

During the due diligence process, IVC firms focus on reducing uncertainty (Blum, 2014). Due diligence is measured by the total hours spent performing research on the portfolio company (Wiltbank et al., 2009). Before making a financial investment, the IVC firm performs extensive research on the portfolio firm's product line, management team, and internal and external competitive environments (Lehtonen & Lahti, 2009; Wiltbank et al., 2009). For example, the IVC might:

- Review background of key management,
- Conduct target market analysis,
- Analyze current and past financial statements,
- Assess competitive advantage and market trends,
- Determine if the portfolio firm has a scalable technology,
- Locate pending legal action,
- Review provisional and approved patents,
- Ensure the portfolio firm product serves an everyday need,
- Research comparables from online venture capital databases to determine valuation price, and
- Evaluate similar portfolio firms in the market before deciding to invest (Blum, 2014).

The time spent by IVCs conducting due diligence is generally proportionate to the anticipated investment funding size (Wiltbank et al., 2009). According to Lehtonen and Lahti (2009), the time from screening to early funding can take approximately 6 months. Yung (2009) countered that the average was closer to 3 months. IVC performing extensive due diligence are more involved in the postinvestment operations of the portfolio firm and experience significantly higher return on investment through a successful exit (Wiltbank et al., 2009). Wiltbank et al. stated IVCs who focused on early funding opportunities experienced few negative exits.

Monitoring Performance

IVCs can reduce asymmetry of information by participating in the management and operations of the portfolio firm. IVC firms invest equity capital without a guarantee of a return on investment (Rajan, 2010). The goal of monitoring is to enhance IVC return on investment and add value to portfolio companies (Rajan, 2010). Participation involves monitoring operations by overseeing, analyzing, and critiquing financial performance and defining strategies and markets (Wiltbank, 2008). IVCs add value by sitting on the board. As board members, the IVC works closely with the portfolio firm's management team, acting as a sounding board, and providing strategic advice. Another example would be for the IVC to utilize established business networks to help the portfolio firm obtain new customers, hire key personnel, or to engage with strategic partners (Rajan, 2010). The IVC also adds value during the exit process by helping to locate investment bankers and in successfully presenting the portfolio company to public or private investors (Rajan, 2010).

Possibly the most critical value addition that an IVC can provide to the portfolio firm is enabling an initial public offering (IPO), strategic merger, sale, or acquisition (Rajan, 2010). Large private equity and IVC investors have well-connected networks and possess an in-depth understanding of the capital markets (Rajan, 2010). Therefore, if the portfolio company wants to list as an IPO, acquiring the best merchant banker and the ability to value the portfolio firm correctly is vital to raising the expected funds (Rajan, 2010). The IVCs' goal throughout the entire investment process is to focus on reducing asymmetry of information, contribute knowledge and expertise to the portfolio firm while achieving large financial returns on investments (Rajan, 2010; Wiltbank, 2008).

THE PROBLEM

Biofuels are an abundant and sustainable source of fuel worldwide. In 2013, the global biofuels market size was 97.8 billion U.S. Dollars (Statista, 2014). Without modification to current systems, biofuels can replace petroleum as a primary fuel source. However, for the IVC, high economic uncertainty exists when investing in biofuels influencing decision-making and inhibiting IVCs from achieving greater levels of successful exists (Li & Mahoney, 2011). Current best practice strategies focuses on reducing asymmetry of information vis-à-vis portfolio firms and are not sufficient to overcome the economic uncertainty inherent in biofuels investing. This paper provides directors and managing partners at IVC firms actionable best practice strategies to reduce economic uncertainty when investing in biofuel portfolio firms.

BEST PRACTICE STRATEGIES

A best practice is the most effective, acknowledged, universal, repeatable, and efficient methods recommended by experts that facilitate an organization's achievement and implementation of a goal (Xu & Yeh, 2012). Alleviating high economic uncertainty requires effective business practice strategies entailing the implementation of business models, quality standards, and product categories that define future market activity (Berglund, 2011). Expected returns models in terms of multiples, net present value, internal rate of return, and the venture capital model are best practice strategies if implemented, permit IVCs to reduce economic uncertainties when in investing in biofuel firms.

Expected Returns Models

Multiples

Regardless of the investing stage, IVCs require at least multiples of 3x meaning three times return on revenue, or 3x gross margin, or 3x the net profit at exit. Some later stage IVCs might accept 2x, while most early stage IVCs expect a minimum 3x on revenue (Blum, 2014). Multiples range from 3x to 10x is the most appropriate model to reduce uncertainty for most biofuels investing (Blum, 2014). For example, if an IVC invests \$10 million in Year 1 and the portfolio firms exists in Year 3; the IVC expects to earn approximately \$40 million in gross profit. IVC firms measure portfolio firm revenue while tracking the amount of funds rose from investors (Blum, 2014). Venture capital funds accounts exist for 10 years and IVCs expect a successful exit within 2 to 5 years of initial funding (Blum, 2014).

Net Present Value (NPV)

NPV is the sum of the present values of a project's cash flows with the present values found by discounting all inflows and outflows at the project's cost of capital. If NPV is zero or higher, the project should be accepted, if the NPV is less than zero, the project should be rejected. Note, a unique discount rate does not exist that will always be suitable for the calculation of NPV for biofuel firms. Different discount rates will be appropriate for different purposes. In specific applications related to biofuels, the correct discount rate to use will often be a specified interest rate or rate of return. Table 1 is the formula for calculating NPV.

Table 1: NPV Formula and Example

$NPV = -C_0 + \frac{C_1}{1+r} + \frac{C_2}{(1+r)^2} + \dots + \frac{C_T}{(1+r)^T}$	
- C ₀ = Initial Investment	
C = Cash Flow	
R = Discount Rate	
T = Time	
Example:	
$NPV = 10,000,000 + \frac{1,000,000}{1 + 10\%} + \frac{1,500,000}{(1 + 10\%)^2} + \frac{2,500,000}{(1 + 10\%)^2}$	

In the example, the initial investment was \$10 million. The expected cash flow for Year 1 is \$1 million with a 10% discount rate. The expected cash flow for Year 2 is \$1.5 million with a 10% discount rate. Total cash flow is \$2.5 million over two years. The NPV for the two-year project is -\$7,438,016.53. In this scenario, the project should be rejected.

Internal Rate of Return (IRR)

IRR also known as rate of return is used by IVCs to compare and measure the profitability of an investment by incorporating the time value of money where a project's NPV = 0 (Blum, 2014). At zero, the project's cash flows are equal to costs. IRR is the discount rate equating the present value of a project's cash inflows to the present value of costs and outflows. Determining the minimum rate of return is known as the hurdle rate. Higher IRR provides the investor with a greater probability of success and a reduction in uncertainty in investing in biofuel firms. IRR reduces the risk of an investment to achieve higher returns on risk adverse alternatives (Blum, 2014). If IRR is greater than the hurdle rate, the IVC should accept the project. If IRR is less than the hurdle rate, the project should be rejected. Table 2 is an IRR estimation based on net income for five years.

Table 2: IRR Estimation based on Net Income

	Project 1	Project 2	Project 3
Net Investment	-10,000,000	-15,000,000	-5,000,000
Year 1 Net Income	5,000,000	1,000,000	1,000,000
Year 2 Net Income	8,000,000	1,500,000	200,000
Year 3 Net Income	1,000,000	1,250,000	250,000
Year 4 Net Income	3,500,000	1,000,050	300,000
Year 5 Net Income	5,000,000	2,000,000	400,000
IRR	39%	-21%	-25%

The IVC should consider accepting Project 1 and reject Projects 2 and 3. The IVC should accept IRR between 36% and 45% return on early stage investments and between 26% and 30% returns for expansion and later stage exits before considering accepting a biofuels portfolio firm project (Manigart et al., 2002). If the interest rate an investor pays to borrow money is less than the IRR, the project should be accepted.

Venture Capital Method

IVCs use the venture capital method to value prerevenue portfolio firms with an anticipated exit within seven years. The method is used by IVCs to estimate an exit price. The venture capital method is calculated as:

$ROI = \text{Terminal Value} \div \text{Post-money Valuation}$. Then, $\text{Post-money Valuation} = \text{Terminal Value} \div \text{Anticipated ROI}$

Terminal Value is the anticipated selling price (or investor harvest value) for the biofuel portfolio firm at a future time, generally 3 to 7 years. Table 3 is an example of using the venture capital method.

Table 3: IRR Estimation based on Net Cash Flows

Discount the Terminal Value to Present Value		
Annual Earnings(Projected NI)	\$10,00,000.00	(at exit date)
In Year	5	(at exit date)
PE(multiple)	15	
Required Rate of Return	25%	
Value of firm	\$49,152,000	
Calculate the Required Ownership Percentage		
Initial Investment	\$4,500,000.00	
Equity Stake	9.16%	
Current Outstanding Shares	1,000,000	(pre)
Total Outstanding Shares	1,100,779	(post)
VC Owns # Shares	100,799	
Share Price	\$44.65	
Pre-Money Valuation	\$44,652,000	
Post-Money Valuation	\$49,152,000	

All investments projects have uncertainty. Implementing expected returns models could reduce economic uncertainty when investing in biofuel firms. While the returns models provide a method to reduce economic uncertainty, all models have limitations. Limitations include all conceivable variables cannot be quantified, too many variables exist to calculate a useful outcome, and multiples comparatives could be scarce. Predicting 3+ years into the future is challenging in determining the portfolio firm's worth in terms of market value, financial performance, and consumer preferences. For IVCs who choose not to use expected returns models, valuations tend to be ad hoc.

CONCLUSION

In this paper, I focused on expected returns models best practice strategies. The models results are only as accurate as the input provided by the IVC. Reducing and prospering from the effects of economic uncertainty requires IVC firms to implement economic best practice strategies. With reduced economic uncertainty, IVCs might be more willing to invest greater funds, and provide knowledge and expertise to nascent biofuel firms benefiting the U.S. economy, physical environment, and social responsibility.
